PROCESS FOR IGNITING COMBUSTION OF FUEL IN THE COMBUSTION

CHAMBER OF AN ENGINE, ASSOCIATED DEVICE AND ENGINE

Field of the Invention

The present invention relates to a process for igniting the combustion of fuel in the combustion chamber or combustion space of an engine ~~and~~, to an associated ignition device and to an associated engine.

Background of the Invention

Because the ignition process has a considerable effect on the efficiency of an internal combustion engine, and especially at a given engine output also largely determines the fuel consumption and pollutant emission, in the past extensive efforts have been made to optimize the ignition process. \_The currently most common ignition devices use spark plugs which ignite the fuel-air mixture.\_ These spark plugs can have one or more electrodes.\_ Each of these electrodes produces an ignition spark which ignites the fuel-air mixture in the immediate vicinity of the electrode.\_ Combustion begins accordingly first in a very small starting volume around the electrodes of the spark plugs.\_ Subsequently combustion propagates with an admittedly limited velocity.

DE 195 27 873 A1 and U.S. Patent No. 5,136,944 describe a glow plug ~~which has~~having a catalytic surface coating of the glow part for reducing the power consumption required for ignition. The ~~disadvantage is that on the one hand~~disadvantages involve the production costs due to the required catalyst materials ~~are being~~increased, and ~~on the other the combustion process is only insignificantly being optimized.~~ ~~US~~ U.S. Patent No. 4,774,914 and U.S. Patent No. 6,595,194 describe an ignition device which is designed to generate an especially large ignition spark.

U.S. Patent No. 4,113,315 describes a two-chamber ignition process, in which the fuel-air mixture is ignited by an ignition source in a first, small ignition space ~~and then.~~ Then, the fuel-air mixture is ignited by the flame propagation ~~which occurs~~occurring in a larger second space, the actual cylinder. ~~US~~ U.S. Patent No. 4,499,872 shows a development of this two-chamber ignition process in which a mixture of ionized water and fuel is ignited using magnetic fields and ignition rods.\_ It is common to the two-chamber ignition processes that they require high construction, and thus, production cost.

U.S. Patent Nos. 5,673,554 and ~~US~~ 5,689,949 ~~discloses~~disclose ignition processes in which microwave energy is used to produce in the combustion space a plasma which ignites the fuel-air mixture.\_ The formation of the plasma is dependent largely on adherence to narrow boundary conditions with respect to formation of a resonant mode; ~~this.~~ This arrangement leads to considerable construction effort, especially with respect to the engine pistons which move up and

down. Moreover, the microwave transmitter limits the path of piston motion in the engine. The corresponding features also ~~applies~~apply to U.S. Patent No. 5,845,480.

U.S. Patent No. 5,983,871 describes a combination of injection of microwave and laser energy for producing the plasma. In this way, the complexity of the ignition device and of the ignition process as well as the pertinent engine ~~are~~is further increased. The corresponding also applies to U.S. Patent No. 6,581,581 which describes a combination of ignition by microwave plasma and magnetic ionization of the atomized fuel-air mixture.

~~It is common to the~~ The known processes ~~that they commonly~~ require complex, and thus, expensive and high-maintenance structures ~~and moreover~~. Moreover, they have only a limited service life. The efficiency of the combustion process, and therefore, of the engine driven by it ~~are moreover~~ limited. In addition, the emission of pollutants is not adequately reduced. In particular, a lower combustion temperature is achieved by the leaning of the fuel-air mixture which has taken place for purposes of reduction of the fuel consumption; ~~this~~. This leaning entails less power. The lower combustion temperature ~~moreover~~also leads to increased pollutant emission.

~~Therefore the~~ Summary of the Invention

An object of the present invention is to ~~make available a~~provide a process for ignition of the combustion of fuel in the combustion space of an engine ~~and~~, the pertinent ignition device and the pertinent engine which overcome the disadvantages of the prior art. In particular, ignition will take place ~~as claimed in the~~according the present invention such that the combustion characteristic is optimized, especially with reduced fuel consumption and reduced pollutant emission at a given power.

The object is basically achieved by ~~the process defined in claim 1 and by the device and engine defined in the subordinate claims~~. Special data for implementation of the invention ~~are defined in the dependent claims~~.

~~\_\_\_\_\_The invention relates especially to a process of or a system for~~ ignition of combustion of fuel in the combustion space of an engine by injecting into the combustion space microwave radiation produced in a microwave source outside of the combustion space,~~the~~. The injected microwave radiation ~~being~~ is absorbed by the fuel distributed in the combustion space, ~~and due~~. Due to the energy delivery into the fuel which occurs due to absorption, the combustion ~~being~~ is uniformly distributed preferably over a large volume in the combustion space and ~~being~~ is ignited essentially at the same time, preferably being uniformly distributed in the entire combustion space and being ignited essentially at the same time.

Generally, ~~in the combustion space there is~~ receives a mixture of fuel and an oxygen source, for example, a fuel-air mixture. By moving the piston in the cylinder, the fuel-air mixture is ~~moreover~~ often compressed during the ignition process. The injection of microwave radiation takes place preferably such that an energy density distribution as homogeneous as possible is formed in the combustion space. For this purpose, either the microwave window can have a comparatively large area or a small-area microwave window can be used. In the latter case, it can be advantageous to provide a diffusion means at the entry point of the microwave radiation into the generally cylindrical combustion space,~~for~~. For example, a suitable flat, point, line or grid structure ~~which~~ causes radiation of microwaves into the combustion space with an isotropic directional characteristic. Optionally, a definable energy density distribution in the combustion space can be achieved by the configuration of the diffuser.

The wavelength of the microwaves is preferably between 0.1 cm and 45 cm, especially between 1 cm and 15 cm and typically between 3 cm and 10 cm. In one preferred embodiment of the present invention, the microwaves are injected in pulse form,~~and for~~. For this purpose, one or more microwave pulses can be used. The power of the microwave pulses depends on the respective application and can be, for example, between one kilowatt and 70 kW. The pulse length can be, for example, between 1 nsec and 2 msec,~~the~~. The pulse distance for several microwave pulses typically ~~being~~ is between 100 nsec and 2 msec.

The supplied microwave energy is used directly for simultaneous and uniform ignition of the entire fuel air mixture. The change of the volume of the combustion space during the pulse interval can be negligibly small due to the pulse duration which is relatively short with respect to the speed of piston motion. The power of the microwave pulses must be selected to be high enough for enough ignition energy to be injected into the combustion space.

The supplied microwave energy heats the fuel droplets present in the fuel-air mixture up to the ignition point, and thus, ignites the mixture. In contrast to the prior art, in ~~this~~the present invention the production of a plasma is avoided.

In contrast to the known ignition systems, in ~~this~~the present invention ignition takes place not at a single given site in the combustion space, and therefore, need not then propagate comparatively slowly, ~~but preferably.~~ Preferably, the entire fuel-air mixture is ignited almost simultaneously and uniformly in the entire combustion space.

In the known ignition process, the combustion process of the fuel-air mixture in the internal combustion engine proceeds in two phases; ~~in~~. In the first phase, comparatively slow, so-called laminar phase, the laminar flame velocity essentially limits the speed of the engine combustion process, and thus, the efficiency. Typical laminar flame velocities especially of modern internal combustion engines with leaned mixture compositions are roughly 10 cm/sec. The laminar phase is followed by ~~the so-called a~~ turbulent combustion phase. From the standpoint of efficiency as high as possible, the second turbulent combustion phase should always be reached as quickly as possible. This is also the focus of some efforts from the prior art, in which as before the first phase must proceed to reach the second phase.

In contrast, according to ~~this~~the present invention the first, slow laminar combustion phase is completely skipped ~~and ignition.~~ Ignition leads directly to the second, high-speed turbulent combustion phase.

~~The~~The present invention also relates to an ignition device for executing ~~the~~this process ~~as claimed in the invention.~~ The electrical power supply source is preferably a pulsed high voltage power pack which makes available the energy required for the microwave pulses. The microwave source can be, for example, a magnetron, klystron, gyrotron, travelling wave tube, (TWT) or the like. Possible microwave connections must be adapted to the wavelength of the microwave source with respect to their dimensions ~~in order to~~ keep reflections and power losses as small as possible. If necessary, the microwave line can also be made flexible.

In one preferred embodiment of the present invention, a coupling means is between the microwave source and the microwave window ~~there is a~~. The coupling means, ~~which on the one hand~~ transmits the microwaves sent by the microwave source to the microwave window, but ~~which on the other hand~~ does not transmit the microwaves reflected by the combustion space back into the microwave source. In particular, this coupling means can have a triple port, especially a circulator with a microwave source connected to its first port, a microwave window connected to its second port and a preferably passive microwave consumer connected to its third port. The circulator ~~has the function of relaying~~relays microwave energy from the microwave source to the combustion space, and at the same time ~~diverting~~diverts the microwave energy radiated back by the combustion space to the passive microwave consumer which absorbs the microwave energy reflected by the combustion space. In this way, the microwave source is protected against reflected microwave radiation. The circulator can contain a gas-filled discharger to improve the function of reducing the microwave energy which has been radiated back.

The microwave window is essentially transparent to microwave energy, in particular high microwave power can also be transported through, ~~and on the other hand it~~. It also seals the combustion space to the outside. One possible embodiment of the microwave window ~~consists in~~ a ceramic disk, a sapphire glass disk or a disk of another suitable material. The microwave window can moreover, for example, have two-dimensional or even three-dimensional structures, preferably on the surface, ~~for~~. For example, by application of a metallic structure ~~by which a~~ definable emission characteristic of microwave energy into the combustion space is ensured.

~~The~~The present invention also relates to an engine with an ignition device which operates according to the ignition process ~~as claimed in~~of the present invention. One special version is an Otto engine, Wankel engine, SIDI (spark ignition direct injection) engine or diesel engine in which a fuel-air mixture in the combustion space is ignited.

This present invention leads to optimum combustion of the fuel-air mixture in an engine ~~as claimed in the invention~~ in that in the entire combustion space, by the simultaneous and uniform ignition and combustion of the fuel-air mixture, a first, slow laminar combustion phase is not formed, ~~but~~. Instead, the second, high-speed turbulent combustion phase is started directly upon combustion. For this purpose, throughout the combustion, space small, turbulent ignition and combustion zones which propagate independently of one another are produced almost simultaneously in a very large number. Accordingly the fuel-air mixture in the entire combustion space is ignited almost at the same time and then burned.

By using several microwave pulses, the fuel droplets present in the fuel-air mixture are heated gradually until the ignition temperature is reached. In this way, basically unwanted different temperature regions in the combustion space are avoided since the gradual increase of the temperature leads to a more uniform, and thus, ultimately practically simultaneous and uniform ignition of the entire mixture in the combustion space. Moreover, basically likewise unwanted plasma generation is prevented by the repeated pulses.

Other objects, advantages, and salient features ~~and details~~ of the present invention will become apparent from the ~~dependent claims and the following detailed~~ description ~~in~~, which ~~several exemplary embodiments are detailed~~, taken in conjunction with reference to the annexed drawings. In this connection, discloses one preferred embodiment of the features mentioned in the claims and in the specification can each be critical to the present invention ~~individually for themselves or in any combination.~~

#### Brief Description of the Drawings

Referring to the drawings which form a part of this disclosure:

FIG. 1 ~~schematically shows the structure~~ is a schematic diagram of an ignition device as ~~claimed in the~~ according to an exemplary embodiment of the present invention;

FIGS. 2 to 4 ~~show~~ are graphs of the output of the engine as a function of the reduction in the amount of fuel in the fuel-air mixture (leaning)); and

FIG. 5 ~~shows~~ is a graph of the CO content of the engine as a function of the leaning.

#### Detailed Description of the Invention

FIG. 1 ~~schematically shows the structure of an ignition device as claimed in 1~~ according to an exemplary embodiment of the present invention ~~for a likewise only~~ schematically shown engine 2, ~~of which only~~. Only the cylinder 3 and the piston 4 which moves up and down in it are shown. The piston 4 and the cylinder 3 border the combustion space 5 in which ideally ~~there is a~~ fuel-air mixture is uniformly distributed. In FIG. 1 the piston 4 is roughly at top dead center.

The ignition device 1 comprises ~~first of all a~~ pulsed high voltage power pack 6 with energy which drives the microwave source 7. A first piece of preferably flexible microwave line 8 is connected ~~in the manner of~~ by a flange to a first connecting flange 9 of the circulator or coupler 10. On the side opposite the first connecting flange 9, the circulator 10 has a second connecting flange 11 ~~which is connected in the manner of~~ by a flange to a second ~~microwave line 12 which likewise is,~~ preferably flexible and leads microwave line 12 leading to the microwave window 13.

The microwave window 13 is fixed on the jacket surface of the cylinder 3 such that the microwaves are radiated into the combustion space 5 ~~such that the~~. The energy density distribution in the combustion space 5 is as uniform as possible. In one preferred embodiment, the microwave window 13 ~~consists of~~ comprises a ceramic disk ~~which is inserted in the cylinder 3 such that the combustion space 5 is sealed to the outside.~~ The microwave window 13 can have on its side facing the combustion space 5 structures 14 ~~by which~~ providing a diffuse incident radiation characteristic of the microwaves emitted into the combustion space 5 ~~is ensured~~.

The microwave energy supplied by way of the first connecting flange 9 is supplied via the second connecting flange 11 to the microwave window 13 by the circulator 10 according to the energy flow represented by the arrow 15. That flow is essentially undamped, and is ~~thus~~ injected into the combustion space 5. Reflections ~~which occur~~ occurring in the combustion space 5 can lead to re-radiation of microwave energy via the second microwave line 12 and into the second connecting flange 11. The circulator 10 ~~in this case~~ ensures diversion of the microwave energy according to arrow 16, specifically not back into the first connecting flange 9, but via a third connecting flange 17 connected to ~~which~~ a third microwave line 18 ~~is connected which guides to~~ guide the reflected energy flow to a passive microwave consumer 19. The connecting flanges 9, 11, 17 of the circulator 10 can also be arranged symmetrically at ~~an angular distance~~ distances of  $120^\circ$  in contrast to the ~~representation~~ orientation shown in FIG. 1.

The ignition process ~~as claimed in of the~~ the present invention was tested with an ignition device ~~as claimed in of the~~ present invention on an internal combustion engine. It was a four-stroke Otto engine with four cylinders and a volume of  $1300 \text{ cm}^3$ . The engine output was 63 hp/46.6 kW. In operation with a conventional ignition system, the fuel consumption was roughly 6.5 liters per 100 km.

In this series production engine, the spark plugs were removed, and ceramic disks were used in their place as seals and as a microwave window. The structure of the ignition device 1 corresponded to that of FIG. 1. The internal combustion engine was mechanically connected to an electric generator, so that it was possible to determine the engine output. An ohmic consumer ~~which was~~ located in a water calorimeter was connected to the generator.

FIGS. 2 to 4 show the output of the engine as a function of the reduction of the amount of fuel in the fuel-air mixture (leaning) in three different operating ranges, specifically at full load (FIG. 2), half load (FIG. 3) and one-third load (FIG. 4). The leaning factor is defined as the fraction to which the fuel portion has been reduced, in FIGS. 2 to 4 proceeding from 1/1 to 1/4.5-th. ~~Here it is apparent that~~ These graphs show that, in operation with the ignition device ~~as claimed in of the~~

present invention, the fuel portion in the mixture itself under full load can be leaned by a factor of 3 without the power being reduced; ~~at~~. At one-third load, this factor is even 3.5.

FIG. 5 shows the reduction of carbon monoxide (CO) content in the exhaust gases of the engine as ~~claimed in the~~ of the present invention as a function of the fuel concentration in the fuel-air mixture. Even at a factor of 1, the concentration of CO with 0.05% by volume is clearly less than in a standard engine with a conventional ignition device, where this value is roughly 0.20% by volume. For leaning by a factor of 3, the CO content can be reduced even more, down to 0.02% by volume. This means a reduction of the CO release by a factor of 10. For approximately the same output, the consumption with the ignition process as ~~claimed in the~~ of the present invention was only 2.3 liters of gasoline per 100 km, therefore roughly one third of the consumption with a conventional ignition process.

While one embodiment has been chosen to illustrate the invention, it will be understood by those skilled in the art that various changes and modifications can be made therein without departing from the scope of the invention as defined in the appended claims.

What is claimed is:

PROCESS FOR IGNITING COMBUSTION OF FUEL IN THE COMBUSTION  
CHAMBER OF AN ENGINE, ASSOCIATED DEVICE AND ENGINE

Abstract of the Disclosure

The invention relates to a method which is used to ignite the combustion of fuel in a combustion chamber (5) of an engine (2), by introducing microwave radiation into the combustion chamber (5), said microwave radiation being produced in a microwave source (7) on the outside of the combustion chamber (5). The introduced microwave radiation is absorbed by the fuel distributed in the combustion chamber (5). The supply of energy, in the fuel, arising from absorption, distributes combustion in a large-volume in the combustion chamber (5), preferably in the entire combustion chamber (5) and in a homogenous manner, and is essentially simultaneously ignited. The invention also relates to an associated ignition device (1) and an associated engine (2).
